

Secure Anonymous Tokens

Secure Anonymous Tokens (SATs) can be used to allow users to authenticate to Frame and in establishing Frame sessions using [Frame Session API](#) without prompting users for another set of credentials. These tokens, generated by a secure API call, enable admins to provide their users with access to Frame resources on-demand. Additionally, the SATs can be customized with additional parameters, including data that can be made available in the remote VM. There are many use cases where this type of authentication could be useful, such as software trials, demos, or kiosk experiences.

Overview

Using the SAT API, a web server can request a token on-demand (when a page or endpoint is requested, for example) and provide it to the Frame Session API for custom-tailored sessions, or pass the token to one of our [Launchpad](#), [Launch](#), or [PWA links](#) to instantly log your users in.

Getting Started

Requirements

- Frame administrator access (Customer, Organization, or Account level).

- **Frame Admin API access** enabled at Customer, Organization, or Account level.
 - **Secure Anonymous Token provider** with an assigned Launchpad User role.
 - Customer-specific location (e.g., web server, thin client) to host the custom Secure Anonymous Token API integration requesting SATs from the SAT provider.
1. If Secure Anonymous Tokens are used with a **Named User Subscription**, then the SAT generation request must include a unique user identifier in order for Frame Platform to count the number of named users in a monthly billing cycle.
 2. If Secure Anonymous Tokens will not contain a unique user identifier, then the customer must purchase **Per VM Subscription**.
 3. Customers using Secure Anonymous Tokens and purchasing Microsoft RDS SAL licenses must comply with the reporting requirements if those RDS SALs are purchased via Frame.
 4. Secure Anonymous Tokens *should not be used in combination with* **Personal Drives** and/or **Profiles**.

REST API Credentials

The Secure Anonymous Token API is invoked over REST endpoints to retrieve tokens. This requires an API integration with the proper roles/permissions.

Creating a new API integration

To get started, be sure to login as an administrator to gain access to API settings.

1. There are two ways to create a new API integration:
 - a. From the Dashboard of the desired Frame account, navigate to the **Users** page.
 - b. If you start from the Frame Admin console, you can navigate to either the **Customer** or **Organization** page and select **Users** from the left-hand menu.
2. Enable the “API” toggle and **Save**.

1. A new **API** tab will appear. Click on the **API** tab and then click the **Add API** link.

4. Give this new API integration a name; for this example, we'll use “API to create anonymous tokens”. Then, select a role and scope based on your scenario below.

For account-level integrations, choose the `API - Generate Anonymous Account Token` role, along with the account you're configuring access for.

For organization or customer level integrations, you'll need to specify the `API - Generate Anonymous Organization Token` and `API - Generate Anonymous Customer Token`, respectively.

5. Click **Add**. The new API will show up in the API list. Click the options menu for the new API and select **Manage Credentials**.

6. You'll be prompted to create a new API key - start by giving it a name, then click the **PLUS ("+")** button on the right.

7. You'll now see your Client ID and Client Secret. Copy these values to somewhere safe, as you won't be able to see the secret again after leaving this screen.

8. That's it! Now you're ready to add a SAT Provider in the next section.

Creating a Secure Anonymous Token Provider

1. There are two ways to create a Secure Anonymous Token Provider:
 - a. From the Dashboard of the desired Frame account, navigate to the **Users** page where you will land on the **Authentication** tab.
 - b. If you start from the Frame Admin console, you can navigate to either the **Customer** or **Organization** page and select **Users** from the left-hand menu.
2. Enable the Secure Anonymous option under Authentication and save; a new **Secure Anonymous** tab will show up.

3. Click the Secure Anonymous tab, then click the **Add Provider** button to the top right.

4. You'll be prompted to describe and configure your new Secure Anonymous provider. You can specify the following:

Property Name	Description
Description	A short description of what you plan to use the Anonymous Token provider for (e.g., public trials)
Token Duration	How long until the token expires and is no longer valid.
Roles and Scope	The role will typically be a Launchpad user, and the scope is which account/Launchpad

5. Give it a description that makes sense for your use case, e.g. "Token provider for product trials". Then, set the token duration you'd like. Finally, select a Role and scope - we recommend only configuring the role for Launchpad Users for security reasons.

6. Your new Anonymous Access Provider will appear. Click the ellipsis next to the provider and select "Playground." Test generating tokens using the new provider, as well as code examples, in various languages, demonstrating how to make a request for tokens.

Generating Secure Anonymous Tokens

Now that we have an API Client ID and Client Secret from the API setup steps above, we can use the dynamic code snippet examples provided in the Secure Anonymous Playground. Making a token request is pretty simple. It requires API credentials, making a HMAC signature based on

those credentials, and then a HTTP POST to your SAT Provider's endpoint.

Security Considerations

Requests for SATs should be executed from a secure backend environment. Requests like these should not be made from client-side JavaScript, for example, as the API credentials can be exposed to the public.

It is your responsibility to secure any self-hosted endpoints that process SAT requests. To clarify, there should not be a public URL on the web that prints out free tokens to any visitor – avoiding this and using best-practices will help prevent unauthorized access, abuse of resources, legal issues, or worse.

Code examples

In the Secure Anonymous Playground, we have a examples for requesting tokens written in **Python 3**, **Node.js**, **curl**, **Powershell**, and **PHP**. To try these for yourself, copy an example in your preferred language, then paste in your Client ID and Client Secret, then execute the code. Executing the examples should return a token if everything is configured properly.

Here's an example that prints the output of a SAT request in Python 3:

```
#!/bin/env python

import hashlib
import hmac
import time
import requests
import base64

# Client credentials
client_id = "<Your API Client ID goes here>"
client_secret = b"<Your API Client Secret goes here>"

# Create signature
timestamp = int(time.time())
to_sign = "%s%s" % (timestamp, client_id)
signature = hmac.new(client_secret, to_sign.encode('utf-8'), hashlib.sha256).hexdigest()

# Prepare http request headers
headers = { "X-Frame-ClientId": client_id, "X-Frame-Timestamp": str(timestamp), "X-Frame-Signature": signature }

# Include optional params such as first_name, last_name, email_domain, email or metadata.
body = {
    "first_name": "John",
    "last_name": "Appleseed",
    "email": "john@example.com",
    "metadata": {
        "data": "favorite food: apples"
    }
}
```

```

}
}

# Make request
r = requests.post("https://api.console.nutanix.com/v1/<Entity type here (customer,
organization, or account)>/<Entity ID goes here>/secure-anonymous/<Secure anonymous provider
ID goes here>/tokens", headers=headers, json=body)

# Print the response (a JWT)
print(r.json())

```

Anonymous Token Parameters

You can provide a few **optional** parameters when generating anonymous tokens. These parameters let you customize the information provided in the JWT, allowing you to set properties such as:

Optional Anonymous Token Parameters

Name	Type	Description	Required
first_name	string	"John" for example.	false
last_name	string	"Smith" for example.	false
email	string	Example: john.smith@acme.com	false
email_domain	string	Example: acme.com. This will return xxxxxxx@acme.com.	false
metadata	object	An object containing any additional information you'd like to supply for your users/token.	false

If provided, Frame will use the above information for User Activity, Session Trail, and Audit Trail reports.

For customers who wish to use SATs in virtual computer labs, retail point of sale, and other thin client use cases, the best practice is to set the values for the `first_name`, `last_name`, and `email` parameters in the SAT generation request to values that would allow administrators to distinguish and report on Frame usage across the physical devices.

For example, for retail point of sale, you might set `first_name` to the store ID, `last_name` to the point of sale location in the store, and `email` to `<store_id>.<location_id>@<domain>`.

If the SAT generation requests do not follow this best practice, then administrators will not be able to determine which sessions correspond to which physical devices, as all sessions will be associated with "Anonymous User". This will make it more difficult to troubleshoot performance issues if the endpoint is not easily identifiable.

Using SATs with Launchpad or Launch links

Admins can redirect users to Frame URLs with a **token as a query parameter**. For an example, let's assume we have following Launchpad URL:

```
---USE Backend---  
https://use.difr.com/acme/projects/demos/launchpad/demo-apps  
  
----DEU Backend----  
https://deu.difr.com/acme/projects/demos/launchpad/demo-apps
```

With that URL in mind, let's assume we've received a token from the SAT API. We'd include the token as a URL search query param:

```
?token=YOUR_GENERATED_TOKEN_HERE
```

Result:

```
----USE Backend----  
https://use.difr.com/acme/projects/demos/launchpad/demo-apps?token=YOUR_GENERATED_TOKEN_HERE  
  
----DEU Backend----  
https://deu.difr.com/acme/projects/demos/launchpad/demo-apps?token=YOUR_GENERATED_TOKEN_HERE
```

And, In the case of a Launch link URL like:

```
----USE Backend---  
https://use.difr.com/launch?terminalConfigId=XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX .XXXXXXXX-  
XXXX-XXXX-XXXX-XXXXXXXXXXXX&appId=desktop  
  
----DEU Backend----  
https://deu.difr.com/launch?terminalConfigId=XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX .XXXXXXXX-  
XXXX-XXXX-XXXX-XXXXXXXXXXXX&appId=desktop
```

Appending `?token=GENERATED_TOKEN_HERE` results in:

```
----USE Backend----
https://use.difr.com/launch?terminalConfigId=XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXXX.XXXXXXXXX-
XXXX-XXXX-XXXX-XXXXXXXXXXXX&appId=desktop&token=GENERATED_TOKEN_HERE

----DEU Backend----
https://deu.difr.com/launch?terminalConfigId=XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXXX.XXXXXXXXX-
XXXX-XXXX-XXXX-XXXXXXXXXXXX&appId=desktop&token=GENERATED_TOKEN_HERE
```

With URLs are appended with a token, when a user goes to the URL, Frame will consume the token from the URL and automatically log the user in. URLs like this can be delivered to users in a number of different ways:

- A link on your website (perhaps open the link in a new tab).
- Redirect to these URLs as part of your user workflow (e.g. `example.com/sign-in -\>` generate token from api `-\>` redirect user to Frame URL)
- Send a link as an email -- be sure the token's expiration duration makes sense for security, tokens begin expiring the moment they're generated.

To ensure great user experience, ensure that the generated tokens have the proper roles/permissions to access the Launchpad or resources you're pointing your users to.

Customize auth flow

When using SATs with Launchpad or Launch links, specific metadata **should be specified** to point to customer-built and customer-hosted URLs that control what happens when a user logs out or in from Frame's UIs.

```
{
  first_name: "Jason",
  last_name: "Thompson",
  email: "jason.123456@acme.com",
  metadata: {
    exampleId: 123456,
    language: "EN",
    timezone: "PT",
    favoriteFood: "tacos",
    frame_login_url: "https://example.com/log-back-into-frame",
    frame_logout_url: "https://example.com/log-out-and-thank-you"
  }
}
```

In the example above, we specified `frame_login_url` and `frame_logout_url`. When these are present, we'll honor the values supplied when users are using our UI.

These URLs are used when Launchpad and Launch link users are inactive (no keyboard or mouse activity) for 15 minutes. When this happens, we log the user out and prompt the user with options to **Leave** or **Log back in**, like so:

Additionally, when using the Launchpad, the logout URL is tied to the Logout button from the Profile menu at the top-right of the Launchpad. When a user clicks this, Frame invalidates the user's token and redirects the user's browser to the URL specified in the SAT's metadata

[image.png](#)

To ensure a great experience, the URL supplied for `frame_login_url` should be used to route a user to your website to generate a new token, then redirect the user **back to their original location** with that token. This ensures compatibility between Launchpad, Launch Links, and PWAs while using Secure Anonymous Tokens.

SAML2 Users can also take advantage of these custom auth URLs if they specify these parameters in their identity provider's assertion/claims. The process to do this varies for each identity provider; please refer to your identity provider's documentation about adding custom assertions/claims.

Metadata

You can provide custom information for a user when generating Secure Anonymous Tokens - this type of metadata is often called assertions. A simple Node.js example is available on [Github](#) that demonstrates how to populate metadata and query it after a token's been generated. We'll use code snippets from this repository in examples below.

Populating metadata

When requesting a token, you can supply a metadata object to the body of the request.

```
{
  first_name: "Jason",
  last_name: "Thompson",
  email: "jason.123456@acme.com",
  metadata: {
    should_accept_tos: false,
    frame_login_url: "https://example.com/login_url",
    frame_logout_url: "https://example.com/logout_url",
    exampleId: 123456,
    language: "EN",
    timezone: "PT",
    favoriteFood: "tacos"
  }
}
```

Optional Metadata Parameters

When populating the metadata request body, you can specify a few different options (As shown in the JSON request example above).

Name	Type	Description	Required
should_accept_tos	string	When set to <code>true</code> , you are accepting the Terms of Service automatically. There will be no UI prompt for accepting the ToS if set to <code>true</code> . This default value is set to <code>false</code>	false
frame_login_url	string	URL used when a user attempts to log back in from a closed session. See more here: Customize Auth Flow	false
frame_logout_url	string	URL used when a user logs out of the Frame UI. See more here: Customize Auth Flow	false

Querying metadata

Querying metadata is a simple GET request along with an Authorization header specifying the token. The token must be specified in the "Bearer" format, and the API endpoint is

`https://cpanel-backend-prod.frame.nutanix.com/api/rest/v1/me/assertions`.

```
async function getUserAssertions(token) {
  const result = await axios({
    url:
      "https://cpanel-backend-prod.frame.nutanix.com/api/rest/v1/me/assertions",
    headers: { Authorization: `Bearer ${token}` },
  });
  return result.data;
}
```

Retrieving Metadata from within Windows

This metadata can also be retrieved from within the remote OS environment during a running session. This is made easy through the use of a **session token** that's made available as an **environment variable** labeled as `FRAME_SESSION_TOKEN`. This Session Token is different than

the token used to start the session (and can't be used for starting sessions), but it relates to the same user. This token also requires a different endpoint for querying the assertions. Here's an example of how to do this in Powershell (5.x):

```
# Set TLS compatibility for Powershell 5.x
[Net.ServicePointManager]::SecurityProtocol = [Net.SecurityProtocolType]::Tls -bor
[Net.SecurityProtocolType]::Tls11 -bor [Net.SecurityProtocolType]::Tls12

$sessionToken = "$env:FRAME_SESSION_TOKEN"
$uri = 'https://messaging.frame.nutanix.com/api/rest/v1/me/assertions'
$headers = @{'Authorization' = "Bearer $sessionToken"}

$response = Invoke-RestMethod -Uri $uri -Headers $headers -ContentType "application/json" -
Method Get

Write-Host $response
```

You can query metadata like this in a "pre-session" script and use the supplied information to customize your applications/environment, mount network drives, etc. Refer to the [Scripting documentation](#) for further details.

Viewing Metadata from Launchpad

Anyone can view their metadata from Launchpad from the account profile page. To view the supplied metadata or "assertions," a user can click on their name at the top-right of the Launchpad to open their User menu. From there, click **Profile**. This will take you to the user's profile page - from there, click **Advanced** on the left-hand side. This page shows a table of assertions for the current user, like so:

Revision #6
